

# Photosynthesis

## The *Producers*

- Produce the food (photosynthesis)
- Condition the environment
- Create shelter and habitat

## Photosynthetic bacteria

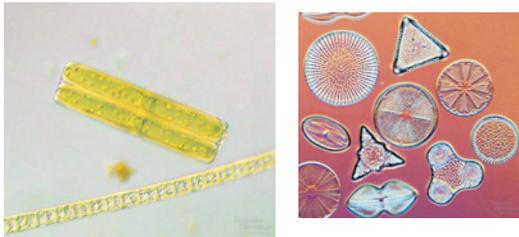

Cyanobacteria —  
“blue-green algae”  
use chlorophyll

Halophilic archaea  
“purple bacteria”  
use bacteriorhodopsin

## Photosynthetic protists

Phytoplankton — earth’s dominant producers!  
• diatoms

## Algae — Aquatic Plants

- Three Divisions (Phyla)

*Chlorophyta*  
“Green Algae”

*Phaeophyta*  
“Brown Algae”

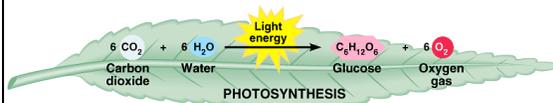

{ including the “kelp” family }

*Rhodophyta*  
“Red Algae”

- Not directly related to each other,  
nor to terrestrial vascular plants.
- Accessory pigments allow greater light sensitivity at depth.

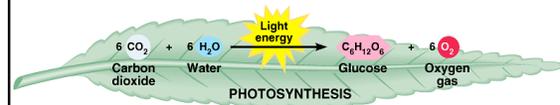

## Photosynthesis

Copyright © 2009 Pearson Education, Inc., publishing as Benjamin Cummings.

- Glucose for energy fuel, organic chemical monomers, structural polymers.
- Oxygen for aerobic respiration.

## Historical perspectives

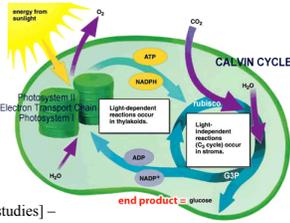

Copyright © 2009 Pearson Education, Inc., publishing as Benjamin Cummings.

- 1600s – JB van Helmont: willow sapling grown in closed container with just watering for 5 years. Tree gained mass without loss of soil mass → gain mass from air.
- 1770s – J Priestly: Discovered oxygen. Discovered that animals require oxygen. Discovered that plants produce oxygen ∴ plants improve the air.
- 1790s – J. Senebier & J Ingenhouz: “Carbon fixation” Plant mass “fixed” from CO<sub>2</sub> in air. Dependent on light.
- 1890s – TW Engelmann: Oxygen specifically produced by chloroplasts. Related to absorption of red & blue light.
- – J von Sachs: Chlorophyll required. Chloroplasts also produce starch. (Derived the equation above)

# Photosynthesis

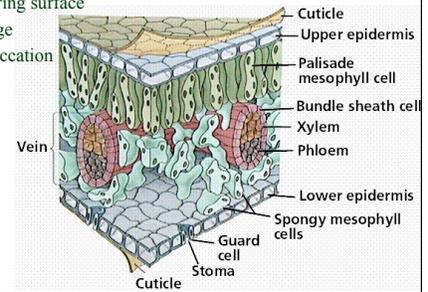

## Historical perspectives

- 1925 – O Warburg: separate “light” and “dark” reactions.
- 1930s – R Hill: Oxygen comes from water, not CO<sub>2</sub>.
- 1940s [advent of radioisotope studies] –
  - SM Ruben, *et al.*: H<sub>2</sub><sup>18</sup>O → <sup>18</sup>O<sub>2</sub> in light-dependent reactions.
  - M. Calvin: <sup>14</sup>CO<sub>2</sub> → sugar in light-independent (“dark”) reactions.
- University of Aberdeen Learning Technology Unit — Photosynthesis  
 – <http://www.abdn.ac.uk/~ch011/flash/samples/photosyn.swf>

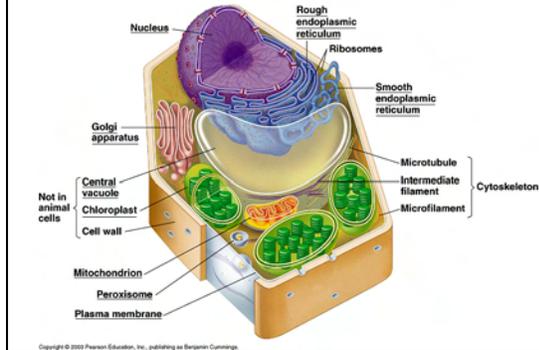

## Leaf: photosynthetic organ of terrestrial plants

- Many tissues
- Specialized structure for
  - Light-gathering surface
  - Gas exchange
  - Reduce desiccation
  - Vasculature

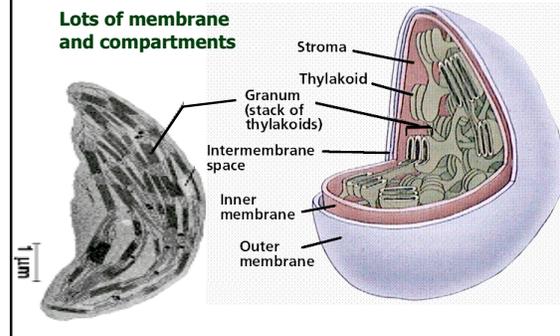

## Plants Cells

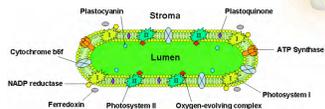

## Chloroplast structure allows photosynthesis to work

Lots of membrane and compartments

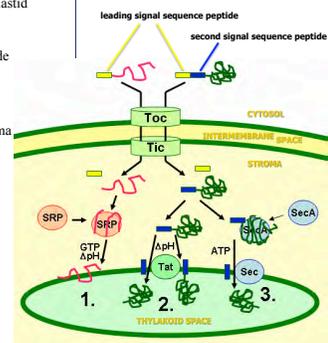

## Molecular machines galore!

- >335 different proteins associated with the thylakoid
  - 89 in lumen
  - 116 thylakoid membrane integral proteins
  - 62 peripheral on stromal side
  - 68 peripheral on luminal side
- most involved in photosynthesis
- but many for targeting, folding, & processing other proteins

## Protein targeting to the thylakoids

- ~95% of plastid proteins coded by nuclear DNA
- Cytosolic proteins targeted across plastid envelope to stroma
  - leading **signal sequence peptide** of a newly synthesized polypeptide as it emerges from the ribosome
  - via protein-conducting channels, **translocon** (T<sub>oc</sub> & T<sub>ic</sub>)
  - signal peptide cleaved off in stroma
- Target to thylakoid membrane or lumen by **second** signal peptide
  - via T<sub>at</sub>
- Stromal DNA-coded proteins may also be targeted to thylakoid
  - via **signal recognition particles** (SRP & SecA)
- Active transport
  - powered by ATP, GTP, or H<sup>+</sup>-gradient cotransport

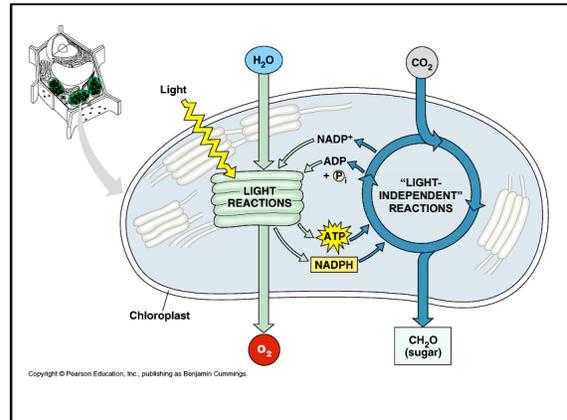

# Photosynthesis

**Photosynthesis:**  
**2 main parts**

- ❖ **1. Light reactions:**
  - in grana
  - light energy → e<sup>-</sup>, ATP
- ❖ **2. Light-independent reactions:**
  - in stroma
  - e<sup>-</sup>, ATP → sugar

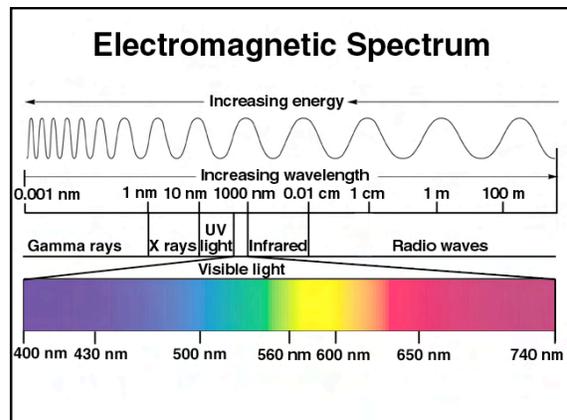

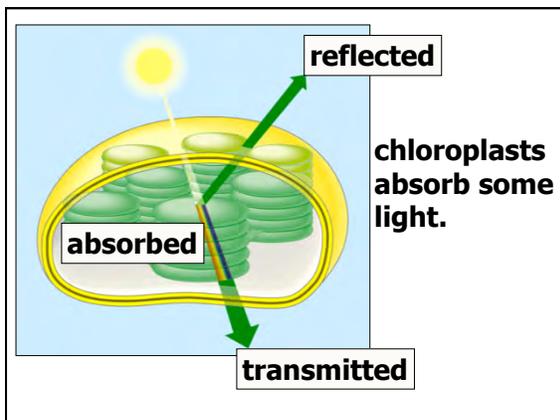

**Photosynthesis:**  
**2 main parts**

- ❖ **1. Light reactions:**  
light energy → e<sup>-</sup>, ATP
  - Photosystem 1
  - Photosystem 2

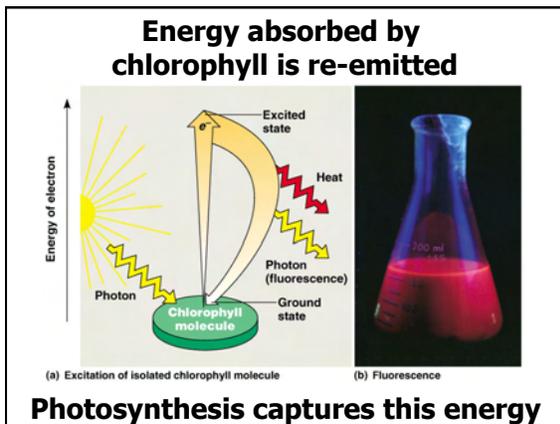

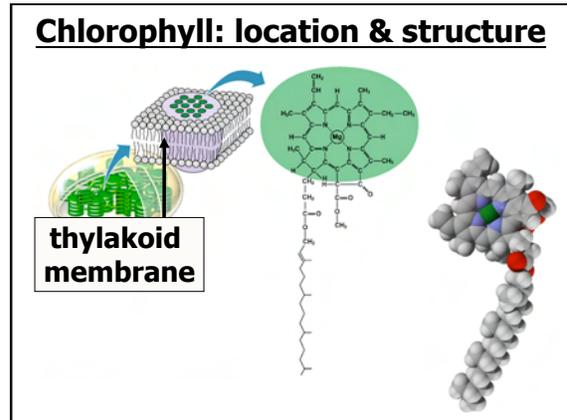

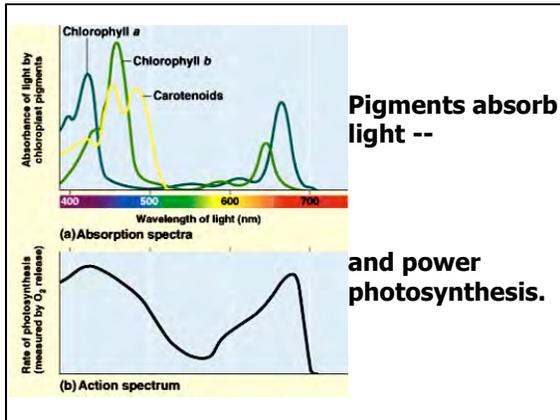

**Photosystem 2**

- ❖ Light excites e<sup>-</sup> in PS2 chlorophyll.

**Light reactions**

# Photosynthesis

- ❖ Light excites e<sup>-</sup> in PS2 chlorophyll.
- ❖ Energy is passed to reaction center chlorophyll.

**Light reactions**

### Photosystems concentrate energy

- ❖ Photons are absorbed by all the pigment molecules.
- ❖ Energy is passed to the reaction center chlorophyll by resonance transfer.

### Photosystems concentrate energy

- ❖ Reaction center chlorophyll loses electrons.

# Photosynthesis

**Photosystems concentrate energy**

Photons are absorbed by all the chlorophylls. Energy is passed to reaction center chlorophyll.

- ❖ Light excites  $e^-$  in PS2 chlorophyll.
- ❖ Energy is passed to reaction center chlorophyll.
- ❖ High-energy  $e^-$  are passed to an electron transport chain.
- ❖  $H^+$  gradient used for ATP synthesis.

**Light reactions**

**Light reactions: noncyclic electron flow**

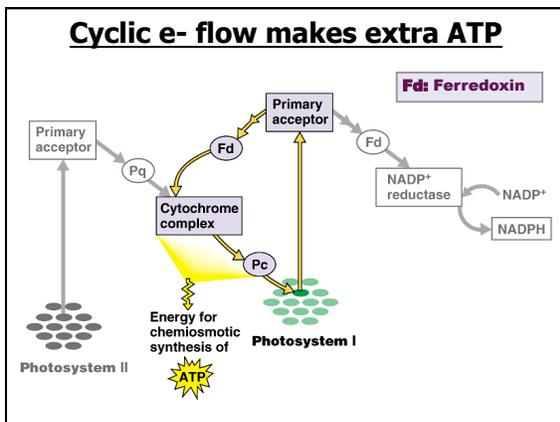

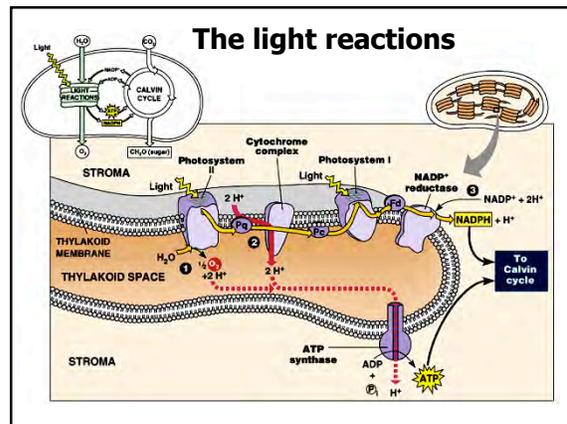

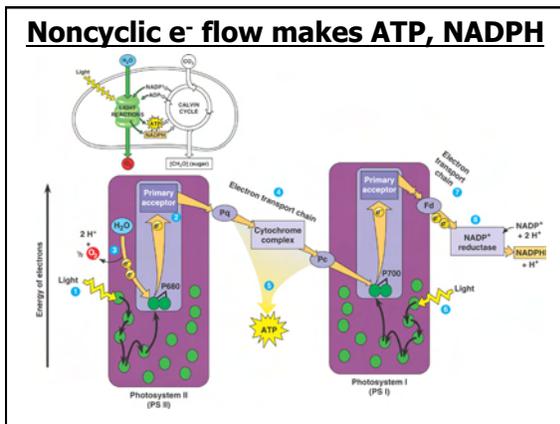

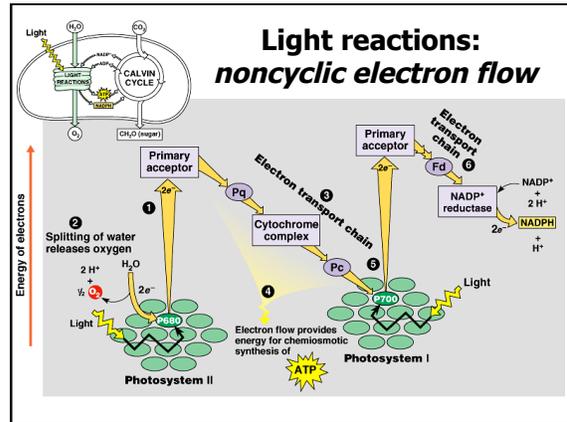

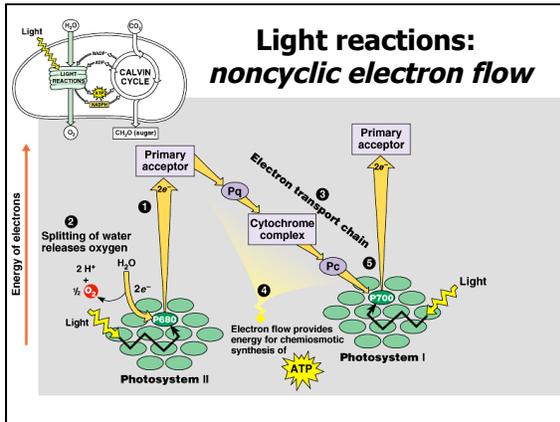

**The light reactions**

**Light reactions: noncyclic electron flow**

- ❖ Light excites  $e^-$  in PS2 chlorophyll.
- ❖ Energy is passed to reaction center chlorophyll.
- ❖ High-energy  $e^-$  are passed to an electron transport chain.
- ❖  $H^+$  gradient used for ATP synthesis.
- ❖ PS1 excites  $e^-$  again;  $e^-$  passed to NADP.

**Light reactions**

# Photosynthesis

**Photosynthesis: 2 main parts**

- 1. Light reactions:** light energy → e<sup>-</sup>, ATP
- 2. Light-independent reactions:** e<sup>-</sup>, ATP → sugar
  - Calvin cycle

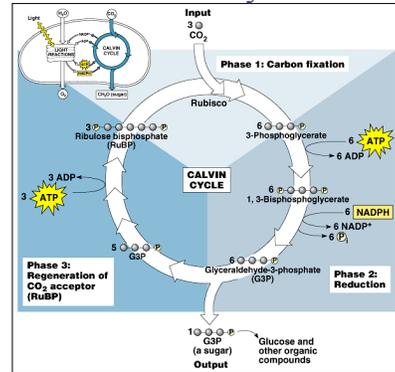

# Photosynthesis

## Calvin Cycle

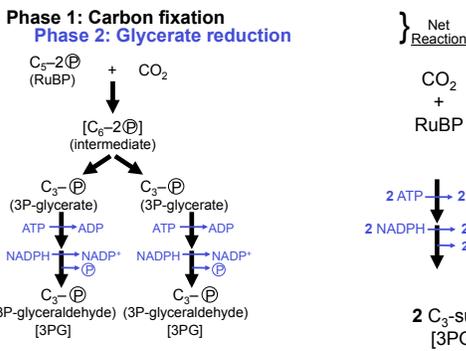

- **Melvin Calvin**, UC Berkeley, 1937–1980
- Nobel prize, Chemistry, 1961
- at Lawrence Berkeley Radiation Lab, used  $^{14}\text{C}$ -labeled compounds to map out complete photosynthetic carbon pathway

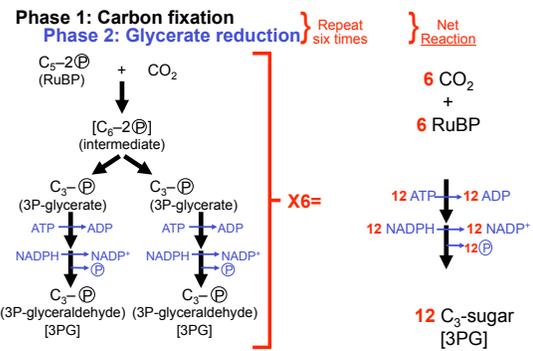

## Calvin Cycle

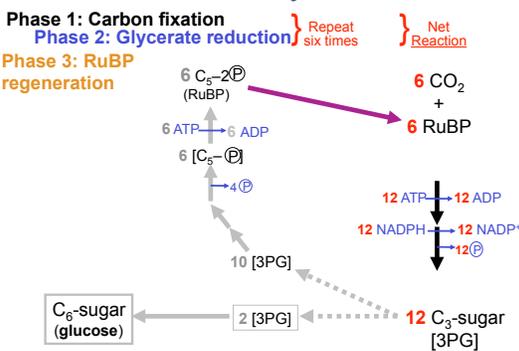

## Calvin Cycle

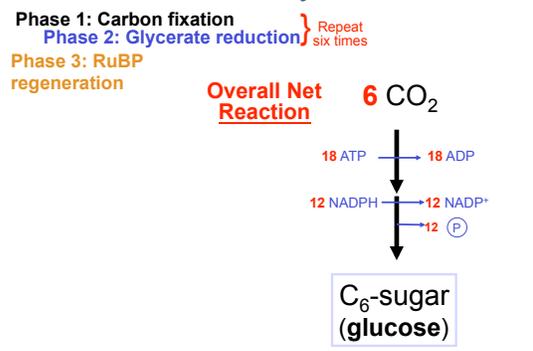

## Calvin Cycle

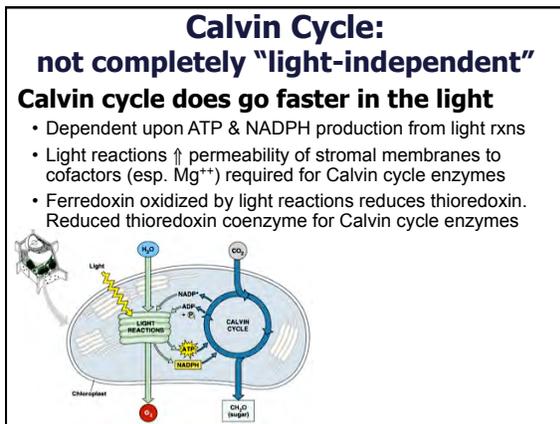

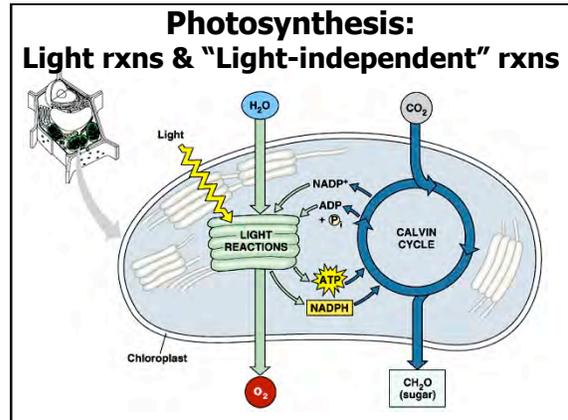

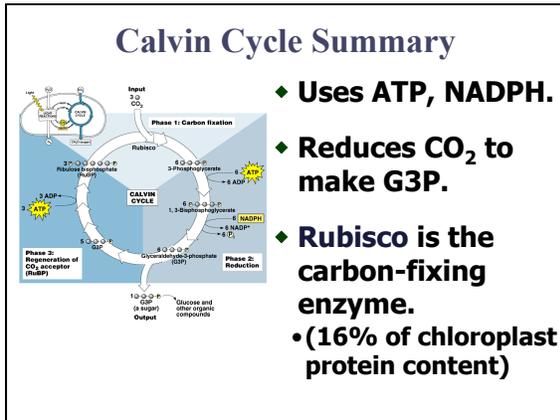

## Calvin Cycle

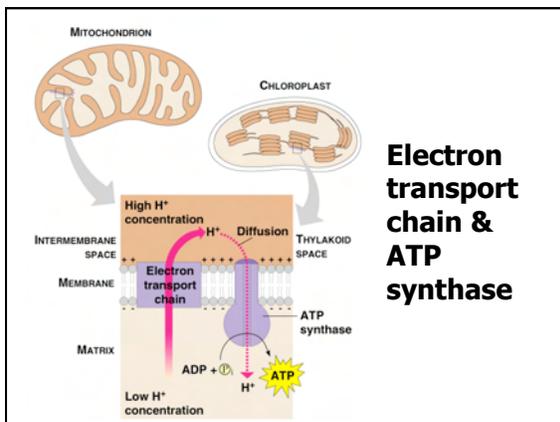

## Calvin Cycle

# Photosynthesis

## Comparing Photosynthesis & Respiration

## Photosynthesis & Respiration

**Similarities:**

- ◆ Both use ETC → proton gradient → ATP
- ◆ Both have redox cycles
- ◆ Both use electron carriers

# Photosynthesis

## Photosynthesis & Respiration

**Differences:**

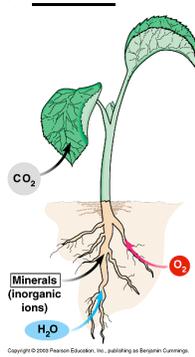

- ❖ **Source of energy, e<sup>-</sup>**
- ❖ **Where e<sup>-</sup> go**
- ❖ **Oxidize vs. reduce carbon**

## **Plants must do both!**

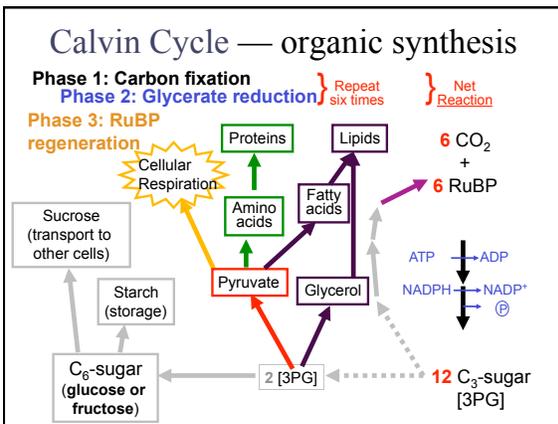

**Gas exchange in vascular plants**

- CO<sub>2</sub> taken *in* and O<sub>2</sub> given *out* by leaves for/from **photosynthesis**.
- Dissolved O<sub>2</sub> taken *in* with H<sub>2</sub>O from soil by roots for tissue **respiration**.

• During daylight: O<sub>2</sub> *out* > O<sub>2</sub> *in*  
 • In dark of night: O<sub>2</sub> *out* < O<sub>2</sub> *in*

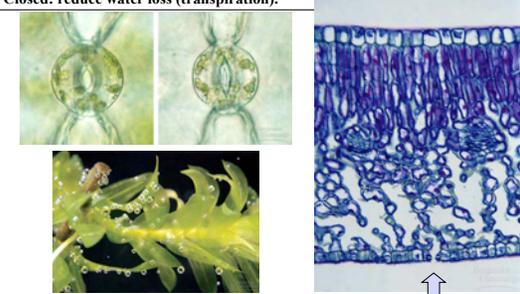

Copyright © 2000 Pearson Education, Inc., publishing as Benjamin Cummings.

### Stomata — “little mouths”

— adjustable openings for gas exchange on the undersides of leaves

- Open: allow CO<sub>2</sub> in & O<sub>2</sub> out for/from photosynthesis.
- Closed: reduce water loss (transpiration).

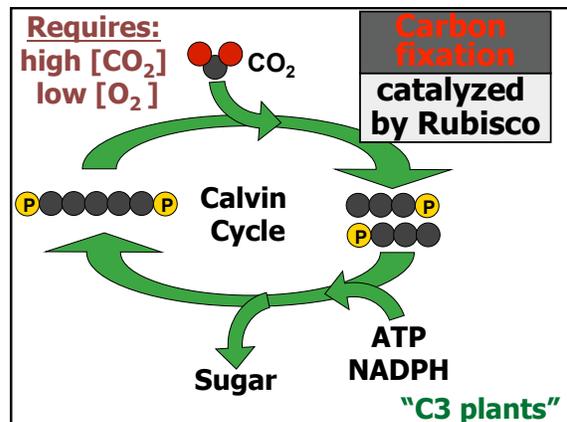

O<sub>2</sub> bubbles forming from stomata

**next:**  
**Photorespiration:**

**When a good enzyme turns bad.**

# Photosynthesis

**Rubisco:**  
ribulose-bisphosphate **carboxylase/oxygenase**

- At typical conditions, **carboxylase** activity is much greater than **oxygenase** activity
  - Add C to Ru-bP
- But at  $\downarrow\text{CO}_2 / \uparrow\text{O}_2$ , **oxygenase** activity becomes greater than **carboxylase** activity
  - **Remove C's** from Ru-bP

$$\begin{array}{c} \text{CH}_2\text{O} \text{P} \\ | \\ \text{C}=\text{O} \\ | \\ \text{H}-\text{C}-\text{OH} \\ | \\ \text{H}-\text{C}-\text{OH} \\ | \\ \text{CH}_2\text{O} \text{P} \end{array}$$

$\xrightarrow{\text{CO}_2}$

$$2 \begin{array}{c} \text{CH}_2\text{O} \text{P} \\ | \\ \text{H}-\text{C}-\text{OH} \\ | \\ \text{C} \\ | \\ \text{O} \text{O}^- \end{array}$$

2(3-phosphoglycerate)

$$\begin{array}{c} \text{CH}_2\text{O} \text{P} \\ | \\ \text{C}=\text{O} \\ | \\ \text{H}-\text{C}-\text{OH} \\ | \\ \text{H}-\text{C}-\text{OH} \\ | \\ \text{CH}_2\text{O} \text{P} \end{array}$$

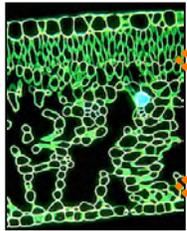

$\xrightarrow{\text{O}_2}$

$$\begin{array}{c} \text{CH}_2\text{O} \text{P} \\ | \\ \text{H}-\text{C}-\text{OH} \\ | \\ \text{C} \\ | \\ \text{O} \text{O}^- \end{array} + \begin{array}{c} \text{H}-\text{C}-\text{O} \\ | \\ \text{C} \\ | \\ \text{O} \text{O}^- \end{array}$$

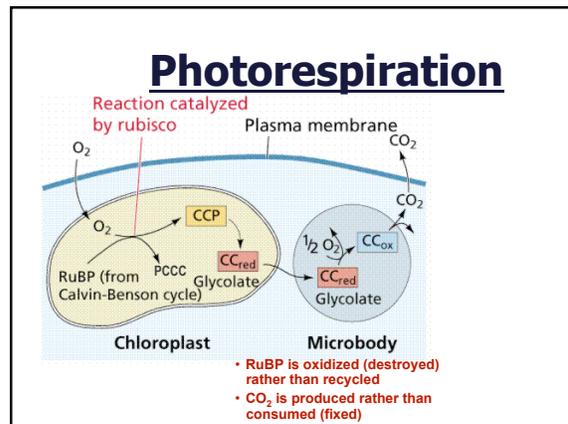

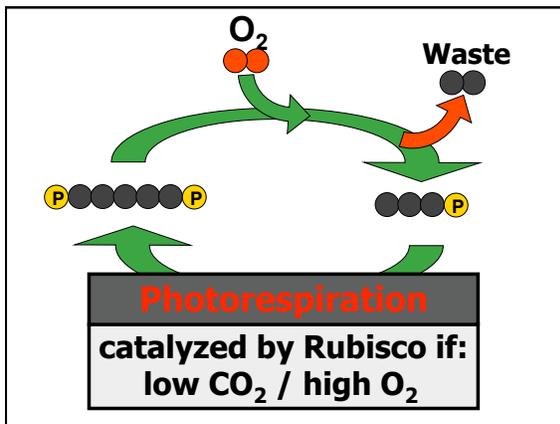

3-phosphoglycerate + glycolate

- Even under good conditions, ~20% of Ru-bP is oxygenated rather than carboxylated

## Photorespiration:

- Stomata close when leaf gets dehydrated to retain water.
- $[\text{O}_2]$  increases;  $[\text{CO}_2]$  decreases.

## Minimizing photorespiration:

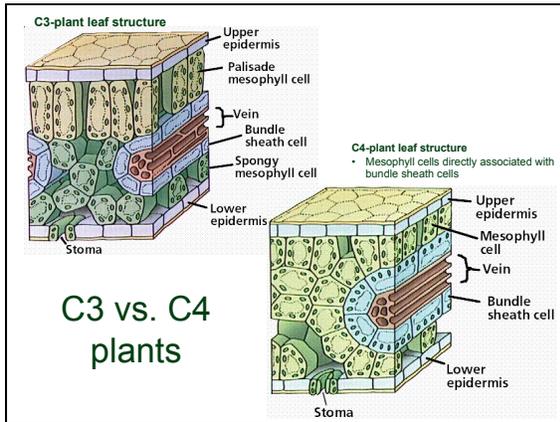

- C4 plants have carbon fixation & Calvin cycle in different cells.

## C4 Photosynthesis

- 1960's — Australian sugarcane researchers trying to replicate Calvin's experiments
- Mostly in tropical grasses
  - Hardy weeds: crab grass, summer annuals
  - Important drought-resistant crops: corn, sugar cane, sorghum
- Independent convergence — Developed independently 45 times!
  - >10,000 spp in 19 families (at least 2 monocot & 14 dicot fams)

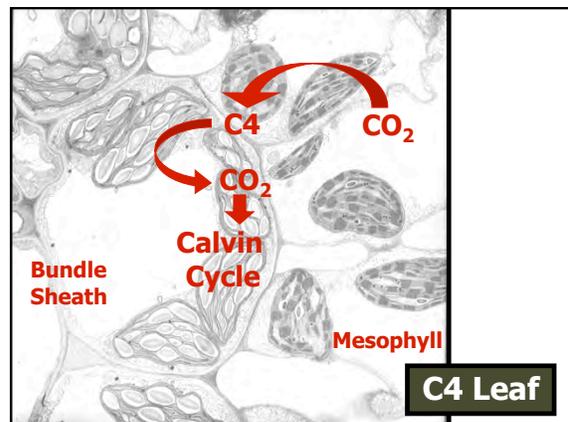

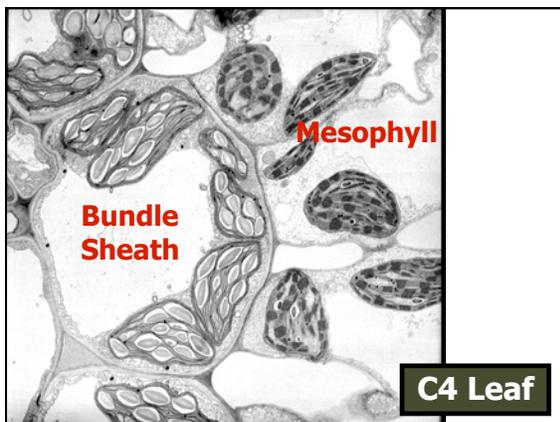

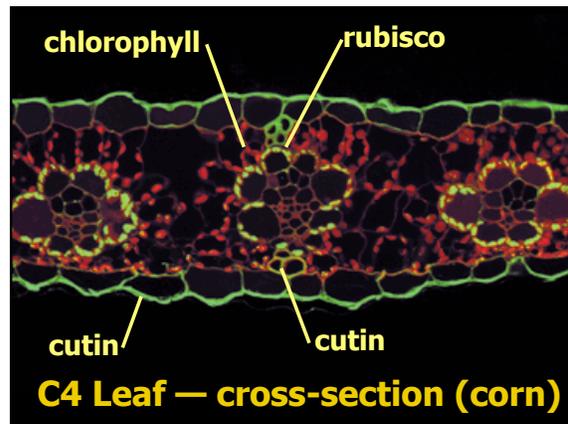

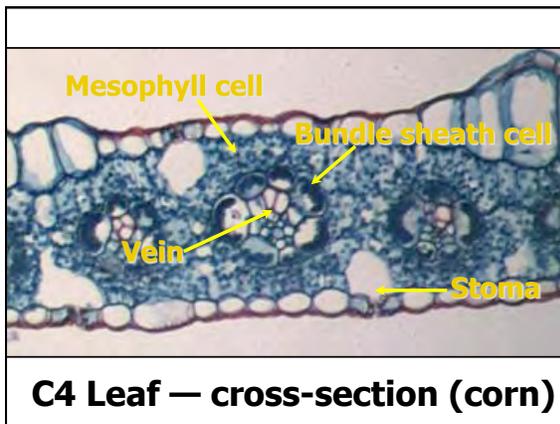

# Photosynthesis

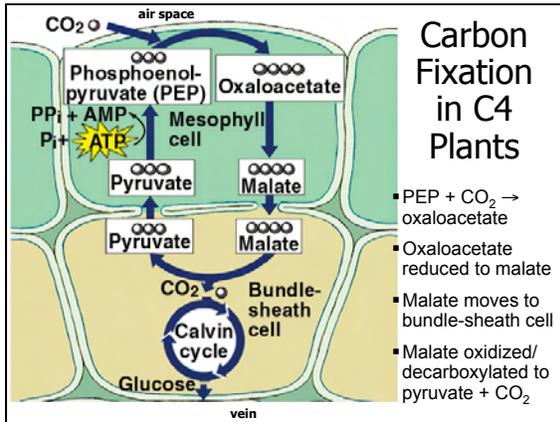

## C4 Photosynthesis

- Photophosphorylation & C<sub>4</sub>-carbon fixation in mesophyll cells
  - PEP carboxylase insensitive to O<sub>2</sub>
  - O<sub>2</sub> from photophosphorylation diffuses back to air space
- Oxaloacetate shuttles CO<sub>2</sub> to bundle sheath cells
- Calvin cycle uses CO<sub>2</sub> for synthesis of organic macromolecules
  - ↑↑CO<sub>2</sub> favors photosynthesis rather than photorespiration
  - Sugars secreted into vascular system

**Called "C4" because first step of carbon-fixation produces C<sub>4</sub>-oxaloacetate instead of C<sub>3</sub>-glycerate**

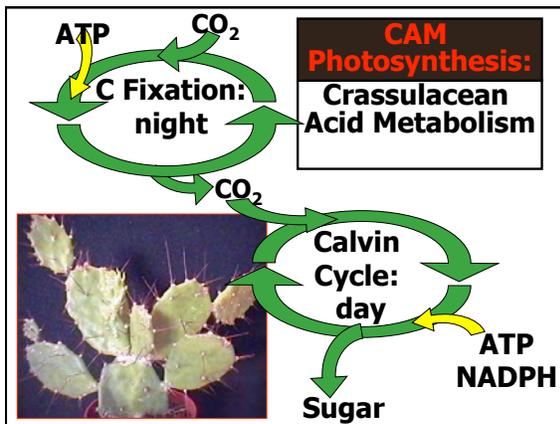

# Photosynthesis

**Minimizing photorespiration:**

- C4 plants have carbon fixation & Calvin cycle in different cells.
- CAM plants do carbon fixation & Calvin cycle at different times.

**Crassulacean Acid Metabolism**

- Ancient Romans noted certain succulents tasted bland in the afternoon, but sour in the morning.
- 1940s: studying South African succulents (Family: **Crassulacea**)

daytime ⇒ ↑ starch / ↓ malic acid  
 nighttime ⇒ ↓ starch / ↑ malic acid

“Crassulacean acid metabolism” (CAM)

*Crassula ovata (jade plant)*

- 1980: CAM model of alternative photosynthesis
- Mostly in desert succulents and tropical epiphytes  
 –Independent convergence again! — >20,000 spp in 33 families!

**CAM Photosynthesis**

- At night—stomata open
  - Starch → [hydrolysis/glycolysis] → PEP
  - C4 carbon fixation: PEP + CO<sub>2</sub> → oxaloacetic acid → malic acid
  - Malic acid stored in vacuole
- At day—stomata close tightly
  - Malic acid released from vacuole
  - Malic acid → pyruvate + CO<sub>2</sub>
    - Pyruvate → back to starch
  - CO<sub>2</sub> increases within cell to 0.2–2.5%
  - ⇒ photosynthesis with minimal photorespiration

**CAM variants**

- **Facultative CAM photosynthesis**
  - During heat of day or dry season: stomata close / CAM photosynthesis
  - During cooler, humid late day or wet season: stomata open / switch to C3 photosynthesis
- **“CAM idling”**
  - During dry season or extended drought, stomata remain closed day and night
  - Extreme recycling!

CO<sub>2</sub> → CAM photosynthesis  
 ↑ ← Respiration ← O<sub>2</sub> ↓

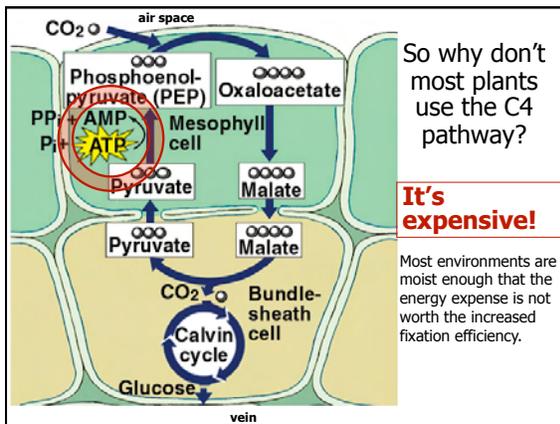

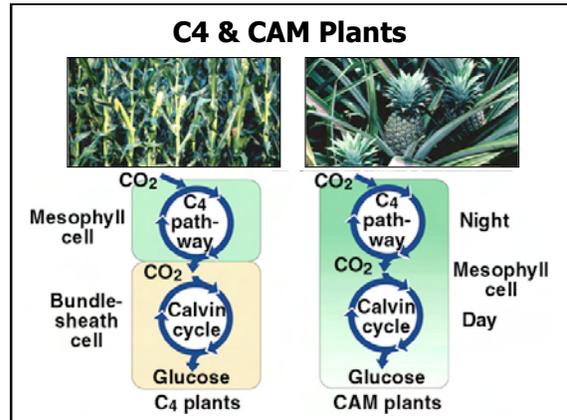

- Not much growth; but can survive for extended periods without any external source of CO<sub>2</sub> or H<sub>2</sub>O
  - Sometimes for years!

# Photosynthesis

**Minimizing photorespiration:**

- ❖ C4 & CAM plants avoid photorespiration by providing more CO<sub>2</sub> for rubisco.
- ❖ They use a separate carbon fixation step before the Calvin cycle.

**Minimizing photorespiration:**

- ❖ Photorespiration can be minimized by providing more CO<sub>2</sub> for rubisco.
- ❖ Many aquatic algae & cyanobacteria concentrate with CO<sub>2</sub>/HCO<sub>3</sub><sup>-</sup> pumps.
  - Pumps activated when CO<sub>2</sub> drops to ~0.03%.
  - Can ↑CO<sub>2</sub> 1000-fold inside cell.

### Chemosynthesis: the other autotrophs

- Some archaea & eubacteria (& fungi?) can fix inorganic carbon into organic molecules *without* sunshine.
- Powered by strong inorganic reducing agents (electron donors).
  - esp., H<sub>2</sub>S, NH<sub>3</sub>, H<sub>2</sub>

$$\text{O}_2 + 4\text{X-H}_2 \rightarrow \text{Electron transport system} \rightarrow \text{ATP \& reduced coenzymes} + \text{CO}_2 \rightarrow \text{Carbon fixation} \rightarrow \text{CH}_2\text{O} + 3\text{H}_2\text{O} + 4\text{X}$$

**Note:** reaction requires O<sub>2</sub> & CO<sub>2</sub>. Still dependent on inputs from photosynthesis & aerobic respiration.

### Chemoautotroph based food webs

$$\text{O}_2 + 4\text{S-H}_2 \rightarrow \text{Electron transport system} \rightarrow \text{ATP \& reduced coenzymes} + \text{CO}_2 \rightarrow \text{Carbon fixation} \rightarrow \text{CH}_2\text{O} + 3\text{H}_2\text{O} + 4\text{S}$$

- In a few regions with no sunlight, little organic carbon input, and a source of H<sub>2</sub>S (e.g., oceanic deep hydrothermal vents), chemosynthetic autotrophs may provide the primary production

- Mats of chemosynthetic bacteria cover the rocks.
- Clouds of chemosynthetic bacteria fill the water column.
- Mouthless tubeworms host symbiotic chemosynthetic bacteria.
- Suspension feeders filter the chemosynthetic bacteria from the water.
- Grazers scrape the chemosynthetic bacterial mats.
